أَلَمْ نَجْعَلْ لَهُ عَيْنَيْنِ

# Role of AS OCT in PAC family

prevalence of PACG 23.36 million and 32.04 million in 2040

80% of cases found in Asia

PACG is a more aggressive form of glaucoma , three times higher risk of blindness

26% of glaucoma cases, it causes almost half of the blindness

**underdiagnosed** worldwide, In China, over 90% of PACG undiagnosed in 2010

frequently **misdiagnosed**, two-thirds of misdiagnosed as POAG in Indian study

25% PACS will progress to PAC in 5 years

30% of PAC will progress to PACG within 5 years

# Role of AS OCT in PAC family

As an adjunct to gonioscopy and evaluation of PAS

Mechanistic evaluation of PACD and treatment outcomes

As A predictor of development of angle closure and IOP fluctuation

AS-OCT of scleral spur.

(A) AS-OCT image showing well-defined scleral spurs

(B) AS-OCT image with poorly defined scleral spurs

**15–28% of AS-OCT unable to identify scleral spur**  
especially in eyes with angle closure

presence or absence of angle closure could still be  
assessed qualitatively in more than 90%

## AS OCT vs Gonioscopy

- significant skill ,(signifcant barrier)
- compliance from patients , contact with the eye
- only fair repeatability , poor reproducibility

- neovascularisation
- real-time dynamic indentation gonioscopy , PAS
- **remains current reference standard for PAS detection**
  - pigment dispersion syndrome
  - angle recession
- 360-degree visualisation of anterior angle

AS-OCT vs UBM. UBM and AS-OCT images of same eye showing ability of UBM to image structures posterior to the iris such as the ciliary body and lens zonules.

- inability to image structures **posterior to the iris**
- difficulty in the manual localization of **scleral spur**
- quantitative parameters cut off points **vary** according to race, sex, device, and definition of angle closure.
- there is no **trend analysis** of the quantitative parameters obtained from AS-OCT.

*Cut off between PAC and Non PAC ???*

# Detection of Primary Angle Closure Using Anterior Segment Optical Coherence Tomography in Asian Eyes

[Winifred P. Nolan, MD, FRCOphth](#)   • [Jovina L. See, MRCS\(Ed\)](#) • [Paul T.K. Chew, FRCS\(Ed\), FRCOphth](#) • ... [Ce Zheng, MSc, MD](#) • [Paul J. Foster, PhD, FRCS\(Ed\)](#) • [Tin Aung, PhD, FRCS\(Ed\)](#) • [Show all authors](#)

Published: October 27, 2006 • DOI: <https://doi.org/10.1016/j.optha.2006.05.073>

## Conclusion

It is highly sensitive in detecting angle closure when compared with gonioscopy.

**More persons are found to have closed angles with AS-OCT than with gonioscopy.**

AS-OCT identified 1 quadrant as closed in 85 eyes that were apparently open in all 4 quadrants on gonioscopy

- Using gonioscopy as a reference standard results in AS-OCT having a sensitivity of 98%.
- This disparity resulted in low specificity for AS-OCT when using gonioscopy as a gold standard.

## several possible explanations

Differences in lighting conditions

Distortion of anterior segment by gonioscopy

Landmarks are not same using 2 methods

A, Both angles are closed when imaging is performed in dark conditions. B, The angle has widened when imaging is repeated with room lights on.

If we turn things around and assess data using AS-OCT as reference standard to examine performance of gonioscopy, we find that gonioscopy has low sensitivity (68.3%) and high specificity (96.6%)

**good sensitivity corresponds to a strong NPV**

a place for AS-OCT in ruling out angle closure

**A negative result**

in situations where a practitioner skilled in gonioscopy is not available

telehealth consultations or in primary care practice

Despite AS-OCT generally showing **specificity above 80%**,  
**prevalence** of angle closure is **low** enough that **PPV was often less than 50%**.  
A positive result becomes difficult to interpret and would necessitate further testing.

Using Gonioscopy As Reference Standard To Define Angle Closure

**We do not currently know**

if these false-positive errors  
are **truly errors**

if they represent eyes at  
**greater risk** of angle closure

### CONCLUSIONS

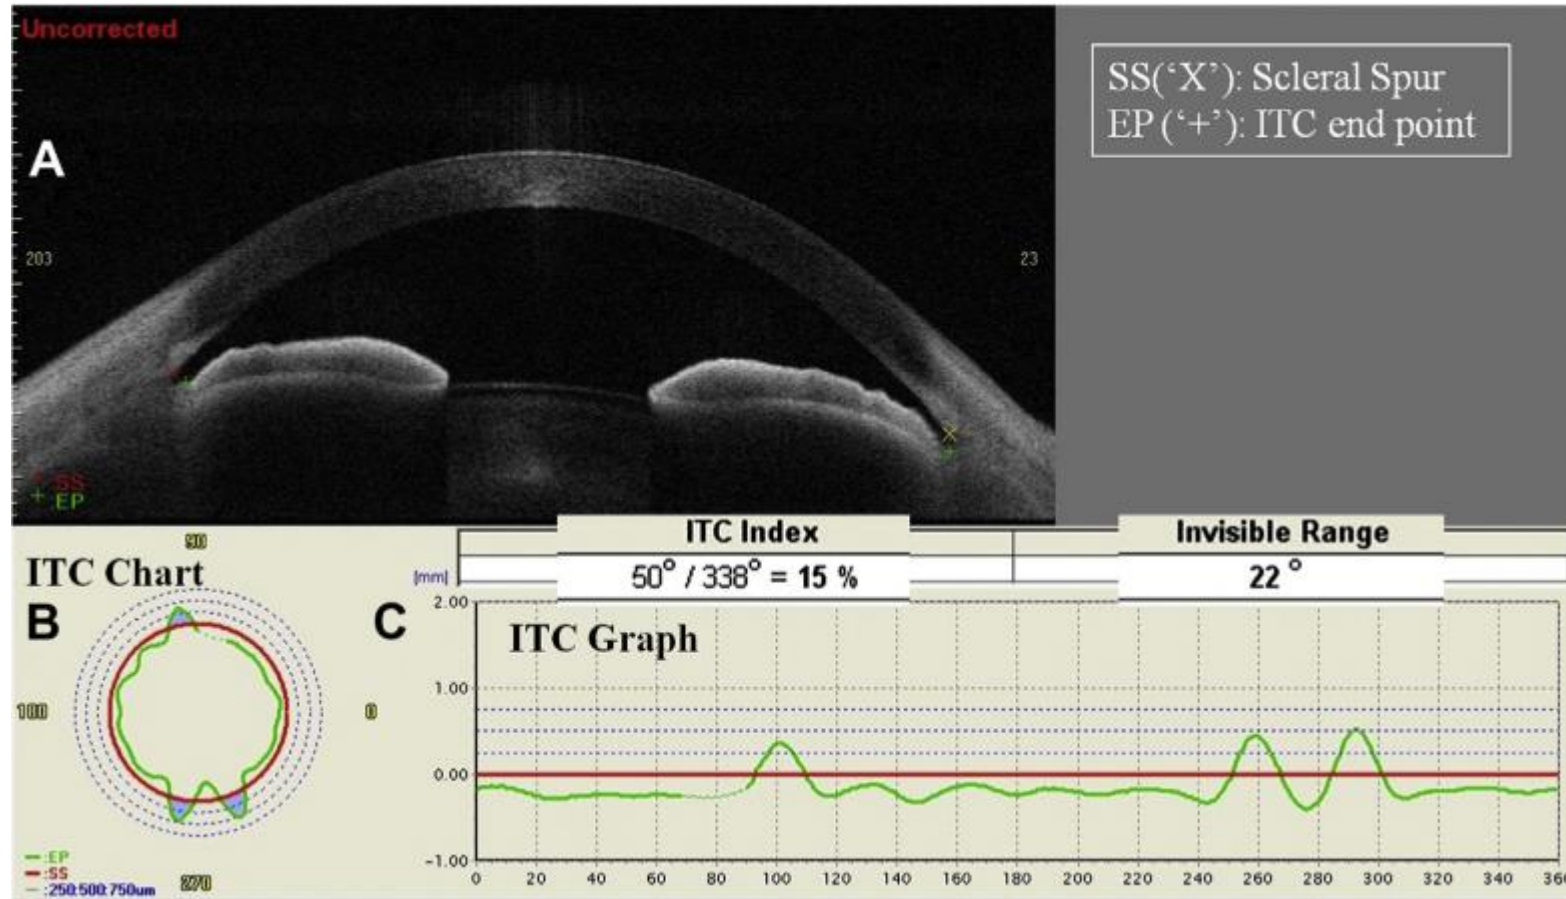

**smaller AOD750 and larger LV** measurements are associated with the development of incident gonioscopic angle closure after 4 years among participants with **gonioscopically open angles at baseline**.

monitoring of patients with evidence of angle closure on AS-OCT, even if the angles appear open on gonioscopy

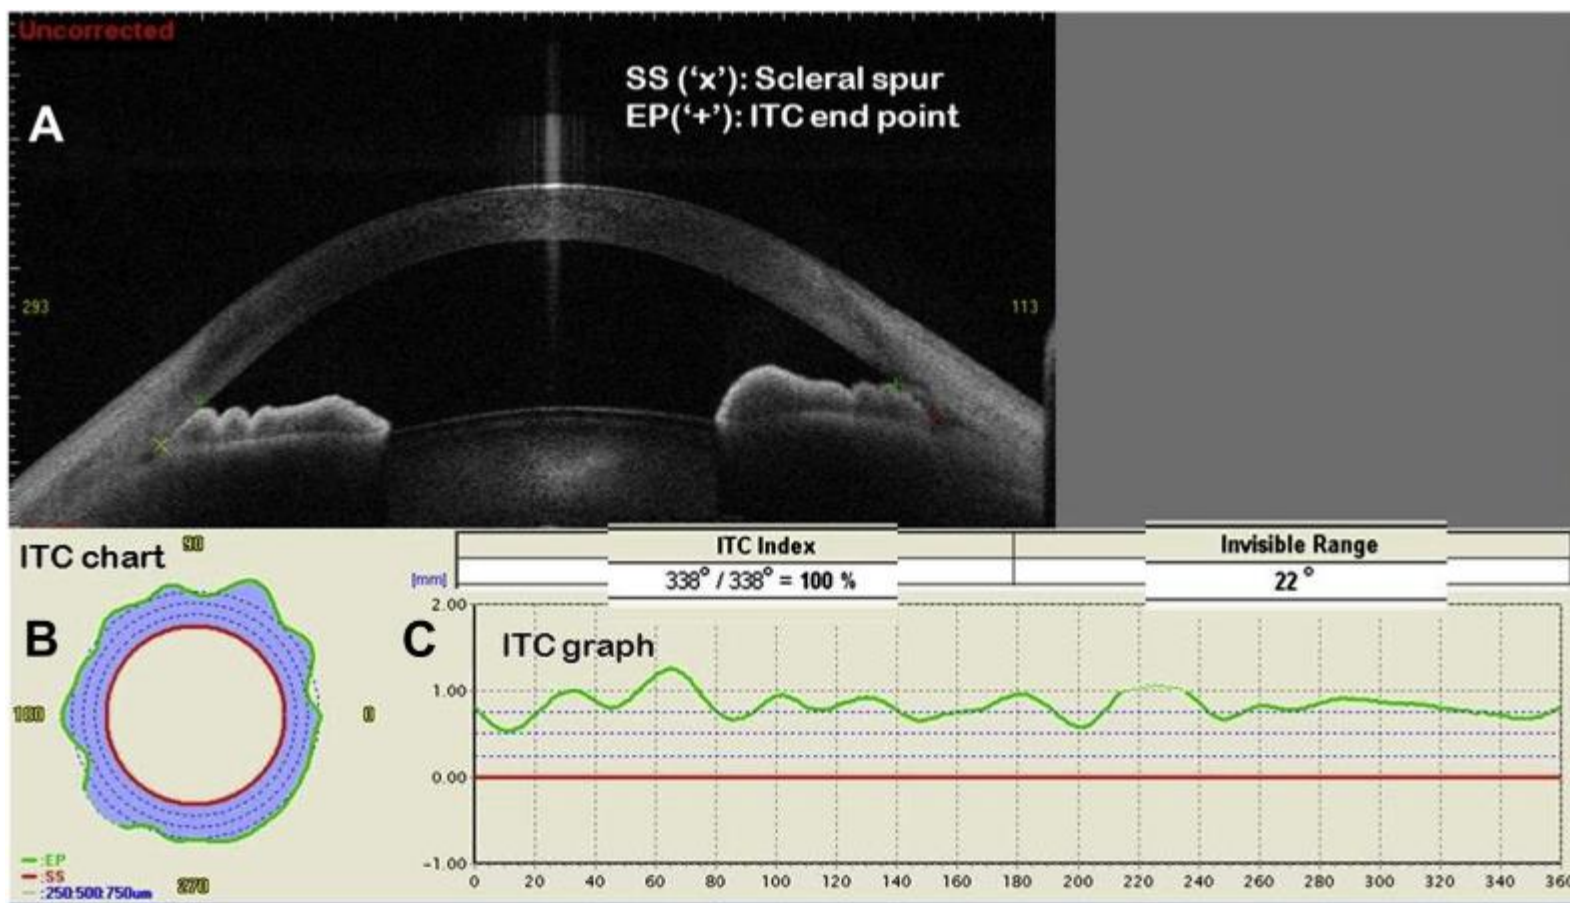

# (ITC) index analysis for an open angle

# (ITC) index analysis for a closed-angle

ITC Result			Close
	ITC Index	ITC Area	AA
Total [0°, 360°)	18.9 % = 68 ° / 360 °	1.723 mm <sup>2</sup>	100.0 %
[-45°, 45°)	0.0 % = 0 ° / 90 °	0.000 mm <sup>2</sup>	100.0 %
[45°, 135°)	40.0 % = 36 ° / 90 °	1.313 mm <sup>2</sup>	100.0 %
[135°, 225°)	35.6 % = 32 ° / 90 °	0.410 mm <sup>2</sup>	100.0 %
[225°, 315°)	0.0 % = 0 ° / 90 °	0.000 mm <sup>2</sup>	100.0 %

Considering angle closure in terms of percentage or degrees could be more accurate than more **limited cross-sectional assessment**.

ITC index showed a higher correlation with postoperative IOP reduction than ITC area, indicating that ITC-induced angle closure itself is more significant than the extent of ITC

**The ITC index of >35%** was found to be optimal for best classification for angle closure across various gonioscopic angle-closure definitions with a sensitivity of 71.9% and a specificity of 84.3% **for 2-quadrant angle-closure**.

discriminate synechial angle closure from appositional angle closure

varying lighting condition

of area and degree of PAS

**Reflectivity Of PAS Appears To Be Higher (Hyperreflectivity)**

indentation gonioscopy remains gold standard to diagnose and quantify extent of PAS

- little correlation between degree of preoperative PAS and IOP control after cataract extraction in PACG.
- Possible explanations include:

- (1) It is **difficult to ascertain extent of PAS** in eyes with a large lens and shallow AC
- (2) Surgical manipulation, such as viscoelastic agent injection and positive flushing pressure may resolve PAS that is of **weak adherence**
- (3) Gonioscopic findings may not truly reflect extent of damage in trabecular outflow pathway as there is loss of trabecular cells and **irregular architecture in areas away from visible PAS.**

- Assessing angle closure is not to solely determine degree of **angle narrowness**
  - but also to evaluate **underlying anatomical and physiological mechanisms** accounting for angle closure.
- more **custom tailoring of therapeutic options** and **anticipation of treatment effects**.

(SS-OCT) scan corresponding to a steep iris profile ('over-the-hill' configuration type) that was assessed as **closed in gonioscopy** but **open in SS-OCT**, representing a **false negative** or undercall case.

# Development of a Score and Probability Estimate for Detecting Angle Closure Based on Anterior Segment Optical Coherence Tomography

Uneven Iris Profile Leading To Irregular ITC

- Measu
- By inco

uenced by iris  
of eye.  
to vary across  
dings

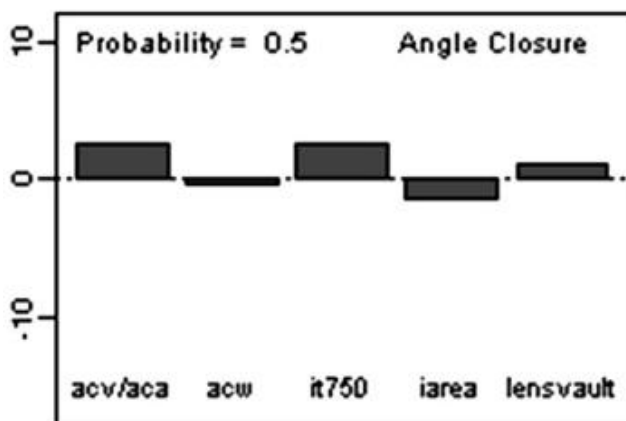

At a low

0.50.  
ises to 0.89.

$$\text{Score} = -28.986879 - 0.339910 \times (\text{anterior chamber volume}) + 3.223506 \times (\text{anterior chamber width}) + 7.296654 \times (\text{iris thickness at } 750\mu\text{m}) - 2.202824 \times (\text{iris area}) + 1.534522 \times (\text{anterior chamber area}) + 0.003242 (\text{lens vault})$$

- Measurements of **angle width** such as TISA and AOD are relatively small and are influenced by **iris contour**; they therefore are subject to **greater variation** around circumference of eye.
- By incorporating **nonangle parameters**, the formula derived in this study is less likely to vary across meridional scans, and therefore more effectively summarizes the AS OCT findings

specificity of 0.96 and sensitivity of 0.75, the estimated probability threshold 0.50.  
At a lower diagnostic threshold of 0.26, specificity drops to 0.89, whereas sensitivity rises to 0.89.

(a) pre- and (b) post-LPI  
There is an increase in **AOD 500** and a  
decrease in **iris bowing**

cautious monitoring for disease progression or intraocular pressure (IOP) elevation despite a patent LPI

angle opening following LPI does not appear to be permanent; angle width narrowed over time, suggesting that nonpupil block mechanisms such as **large LV** may play a role.

eyes with **thin peripheral iris** and narrower angles were associated with greater angle opening following LPI, whereas eyes with **thick peripheral iris** at baseline showed less angle opening after LPI

An ability to select angle closure eyes that would most likely benefit from LPI may aid in **individualizing treatment and reduce unnecessary prophylactic LPI that may not be effective** in opening the angles in some patients.

The distinction between classic pupil block narrow angle and phacomorphic narrow angle is often impossible to appreciate with gonioscopy but may be readily determined with AS-OCT.

AS-OCT lens contour method for narrow angle, classic pupil block. AS-OCT image that demonstrates classic pupillary block

lens contour method for phacomorphic narrow angle. An AS-OCT image that demonstrates classic phacomorphic narrow angle

(EAGLE) study  
CLE for  
➤ Hypertensive PAC  
➤ PACG

# Mixed Pupil Block/Phacomorphic Condition

The decision for optimum treatment strategy would depend on several factors, including the visual **acuity, IOP, cataract severity, presence and extent of PAS**

Regardless of choice, all forms of narrow angle require either laser or surgical intervention.

Topical therapies or observation may be harmfully insufficient in these eyes

residual membrane occluding LI (arrow), though iris transillumination defect is apparent on slit-lamp  
(b) Following an additional (Nd: YAG), LI is patent

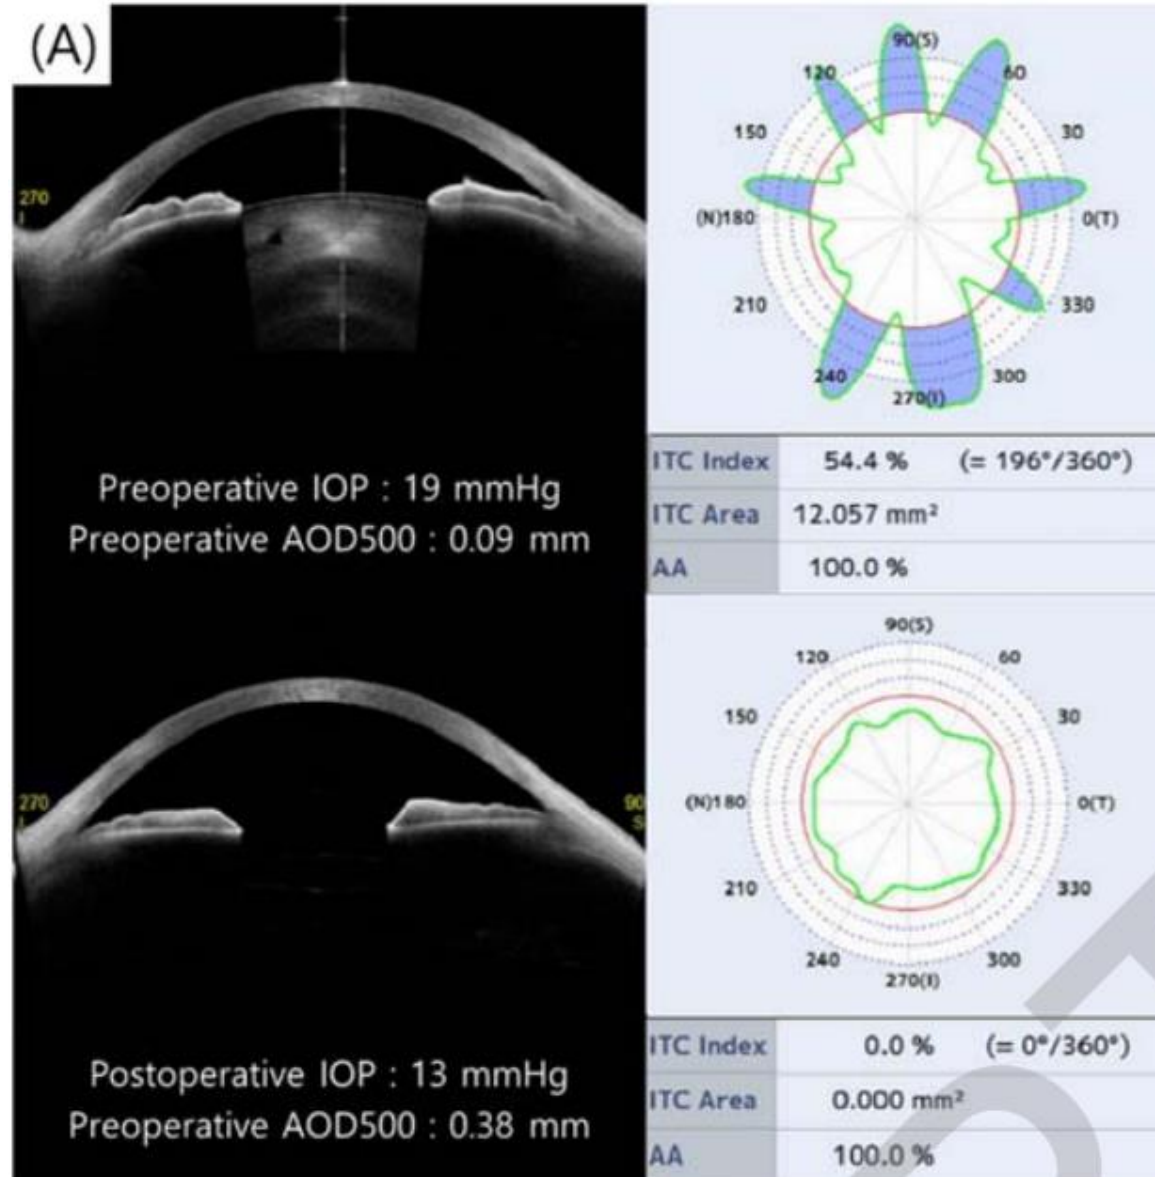

(a) pre- and (b) post-phacoemulsification. There is an increase in AOD 500 and in ACD as well, while there is a decrease in iris bowing after phacoemulsification treatment.

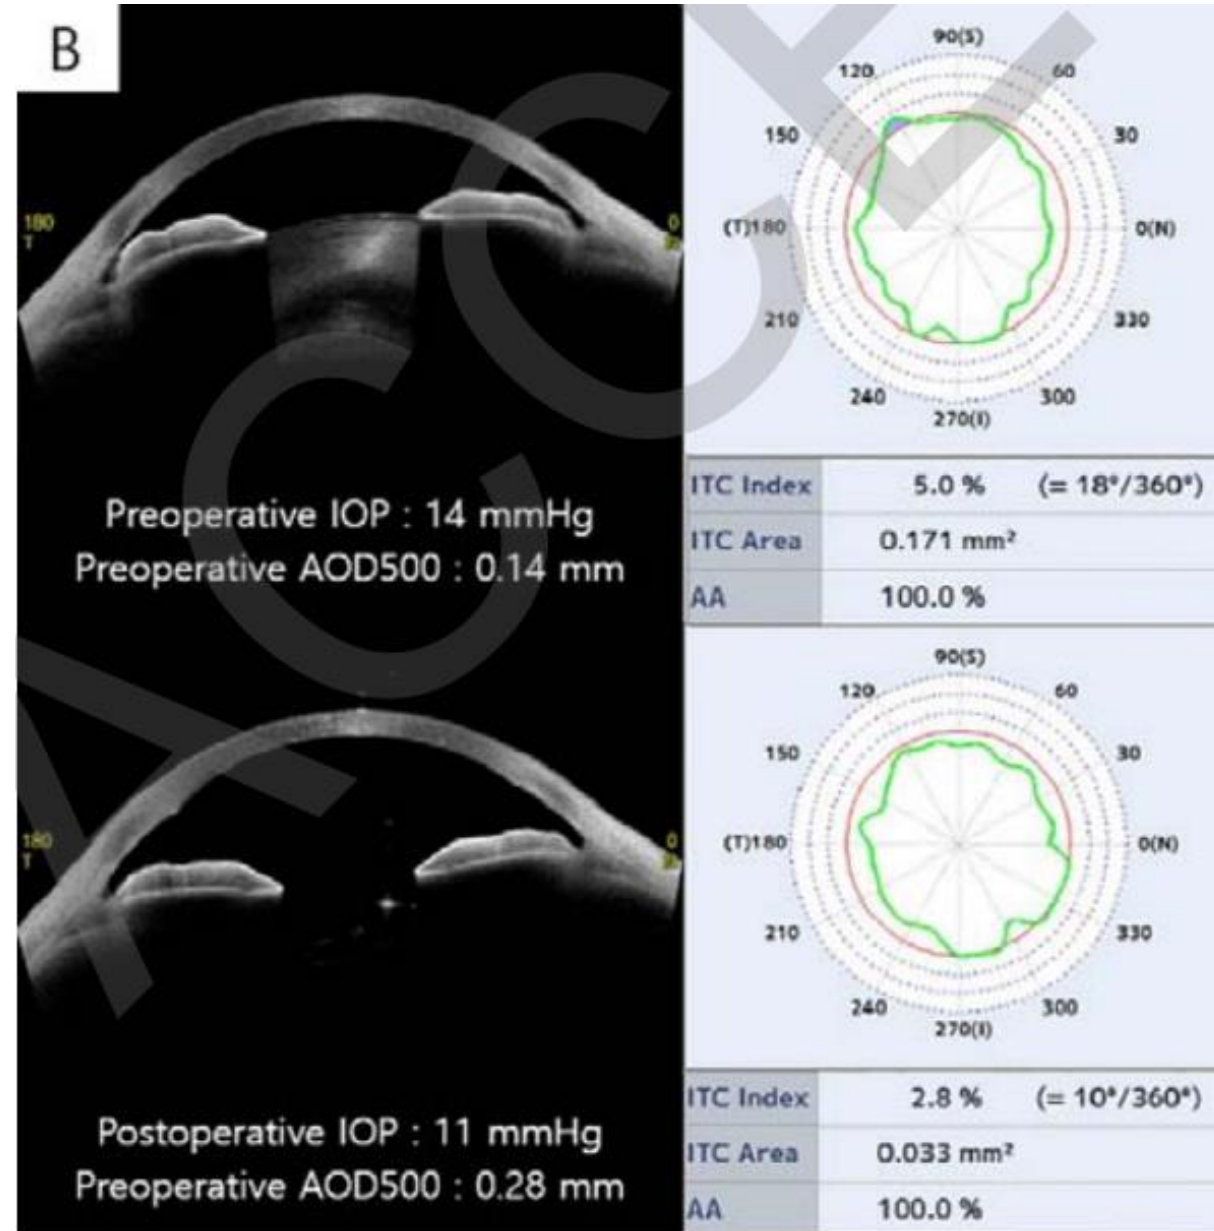

# Anterior chamber angle and IOP control after PE in PACD with different mechanisms

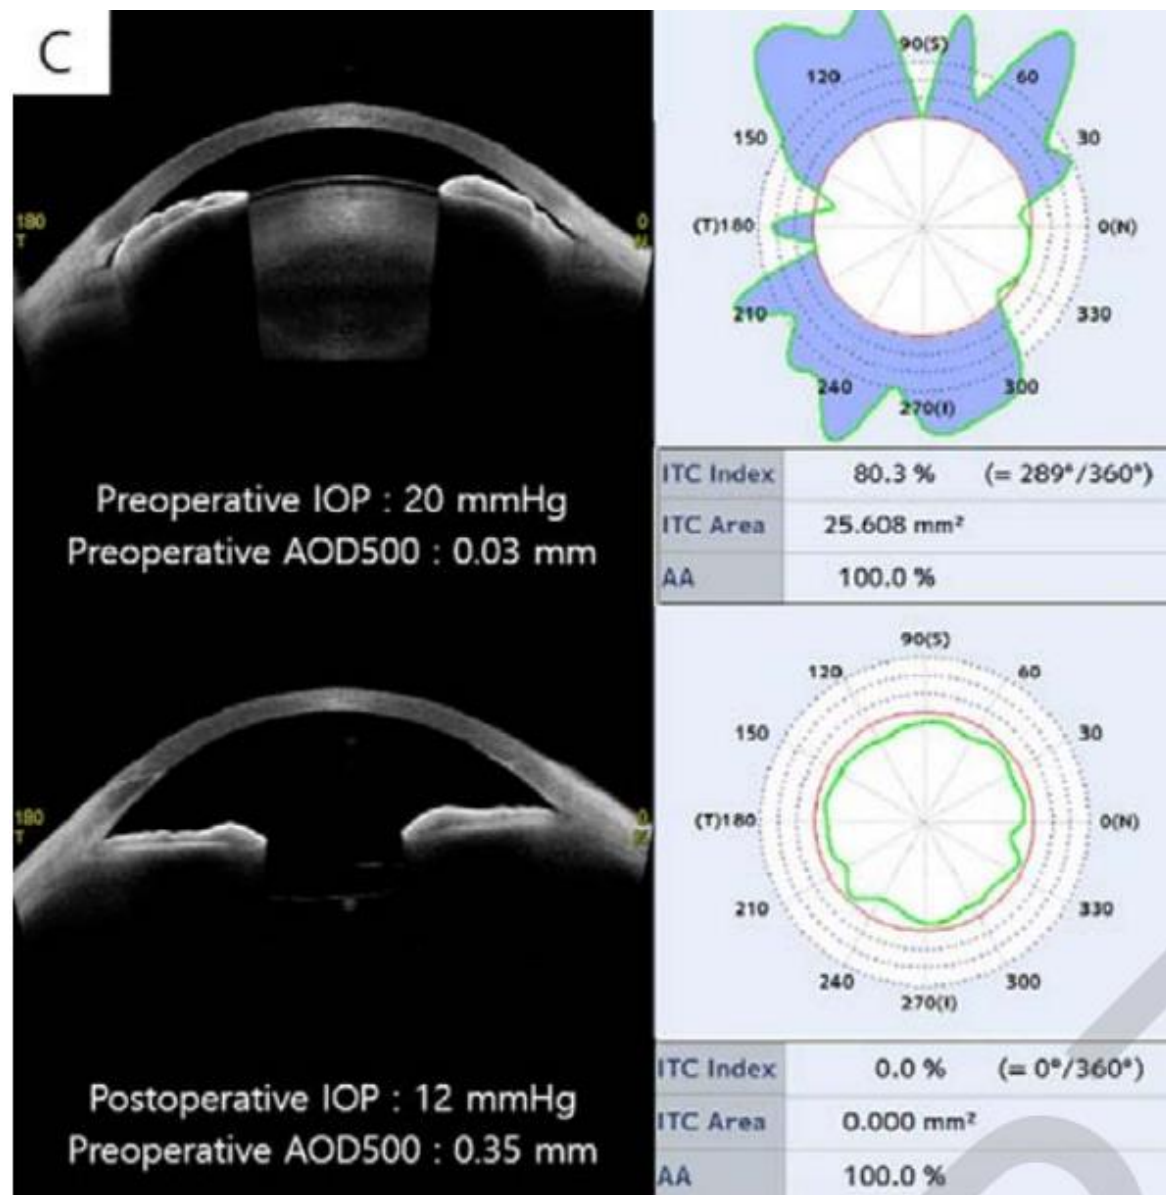

## PB mechanism

## PIC mechanism

## High LV mechanism

As an adjunct to gonioscopy and evaluation of PAS

Mechanistic evaluation of PACD and treatment outcomes

As A predictor of development of angle closure and IOP fluctuation

As evidence for association between anterior segment features and angle closure grows, **use of gonioscopy alone appears to be less and less** inadequate for detecting subjects with angle closure disease.

It is arguable that anterior segment imaging should be considered **first line screening** for patients at risk for angle closure

AS-imaging as a **potential 'reference standard'** (but not replaced) for diagnosis and monitoring angle closure disease
